

**IN THE CLAIMS**

1 (Currently Amended). A method comprising:  
providing a register accessible by a plurality of central processing units; and  
indicating whether data in said register is available for a given central processing unit by providing different indicators assigned to each of a plurality of central processing units and enabling causing the given central processing unit to reset its indicator when the data in said register is no longer useful to the given central processing unit.

2 (Previously Presented). The method of claim 1 including indicating for each of a plurality of central processing units whether the data is available for a given central processing unit.

3 (Previously Presented). The method of claim 2 including requiring a central processing unit to wait to execute an instruction until the data it needs to execute the instruction is available in one or more registers.

4 (Previously Presented). The method of claim 3 including providing a bit for each item of data indicating whether a given central processing unit can access that data.

5 (Previously Presented). The method of claim 4 including resetting said bit when said data is accessed by a given central processing unit.

6 (Previously Presented). The method of claim 1 including preventing any central processing unit from writing data to said register until all of the indicators for the plurality of central processing units indicate that the data is no longer useful to any other central processing unit.

7 (Previously Presented). The method of claim 6 including indicating the central processing unit which will utilize the data written into the register.

8 (Currently Amended). The method of claim 1 includes ~~enabling~~ causing a plurality of central processing units to access a register at the same time.

9 (Previously Presented). The method of claim 1 including providing specialized central processing units for mathematical operations and for memory.

10 (Previously Presented). The method of claim 1 including providing an input central processing unit, an output central processing unit and coupling said input, output and specialized central processing units to said register through a cross-bar connection.

11 (Currently Amended). A computer readable medium storing instructions that, ~~[[if]]~~ when executed, enable a processor-based system to:  
make a register accessible by a plurality of central processing units in said system;  
provide different indicators for each of a plurality of central processing units;  
indicate whether data in said register is available for a given processing unit; and  
~~enable~~ cause the given central processing unit to reset its indicator when data in the register is no longer useful for the given central processing unit.

12 (Currently Amended). The medium of claim 11 further storing instructions that ~~enable~~ cause the processor-based system to determine whether data is available in a register for a particular processing unit.

13 (Currently Amended). The medium of claim 12 further storing instructions that ~~enable~~ cause the processor-based system to prevent execution of an instruction until the data needed to execute the instruction is available in one or more registers.

14 (Currently Amended). The medium of claim 13 further storing instructions that ~~enable~~ cause the processor-based system to check a bit in said register for each item of data indicating whether a processing unit can access said data.

15 (Currently Amended). The medium of claim 14 further storing instructions that ~~enable~~ cause the processor-based system to reset said bit when said data is accessed by a processing unit.

16 (Currently Amended). The medium of claim 15 further storing instructions that ~~enable~~ cause the processor-based system to avoid writing said data to said register until all the bits indicate that the data is no longer useful to any other processing unit.

17 (Currently Amended). The medium of claim 16 further storing instructions that ~~enable~~ cause the processor-based system to indicate which processing unit will utilize the data written into the register by another processing unit.

Claims 18-30 (Canceled).
